#### Abstract

The aim of this paper is Modeling Credit Rating for Bank of Eghtesade Novin in Iran. For do it, we have implied logistic regression for estimation credit model. We have used information about 310 customers for determining the main factors in credit risk. Results indicate that industrial type of loan in which the applicant is one of the most important factors affecting the credit risk of customers. Results indicate that 70 cases ( $92 \%$ of the total 76 cases) classified correctly in observations $\mathrm{Y}=0$ (lack of timely repayment of the facility) and 227 cases ( $97 \%$ of the total 234) classified correctly in observations $Y=1$ (timely repayment of the facility).

Key Words: Credit Rating, Bank of Eghtesade Novin, Logit, Probit, Iran.

## 1. INTRODUCTION

Eghtesade Novin (EN) Bank is Iran's first private bank; established in 2001 by a consortium of industrial, construction and investment companies, with the aim of providing flexible financial services to the burgeoning Iranian private sector.

Ratings are opinions about the creditworthiness of a rated entity, be it a sovereign, an institution or a financial instrument. They reflect both quantitative assessments of credit risk and the expert judgment of a ratings committee. Thus, no rating can be unequivocally explained by a particular set of data inputs and formal rules.

EN Bank is the first private bank in Iran to be rated by an international credit rating agency. The following table shows our ratings by Capital Intelligence for 2009:

[^0]Table 2. EN Bank ratings by Capital Intelligence for 2009

| Foreign Currency |  |
| :---: | :---: |
| Long-Term | BB- |
| Short-Term | B |
| Financial Strength | BB- |
| Support | 4 |
| Outlook | Stable |
| Foreign Currency | Stable |

Ratings convey information about the relative and absolute creditworthiness of the rated entities. Agencies often emphasize that a rating reflects the creditworthiness of the rated entity relative to that of others. That said, agencies regularly publish studies that convey the historical association of ratings and indicators of absolute creditworthiness, such as default rates and the magnitude of losses at default. Moreover, in the case of structured finance products, ratings are explicitly tied to estimates of default probabilities and credit losses.

Many researchers investigated credit rating. Some of most important research are: Peel and Wilson (1986), Altman (1968), (Altman, 1983), (Lin et al., 2007),Bharath and Shumway (2004), Larry and Timothy (1986), Chandy and Duett (1990), Pinches and Mingo (1973), Kaplan and Urwitz (1979), Belkaoui (1983), Kim (1993), Manzoni (2004), Huang et al. (2004), Laitinen, (1999), Doumpos and Pasiouras (2005), Manickavasagam and Srinivas (2009), Patricia and David (2009) and Manickavasagam and Srinivas (2009)

In this paper, we have used Logit regression for EN Bank's credit rating. In the next section, we introduce the method and we show empirical results in section 3 . Section 4 is devoted to conclusion.

## 2. METHODS

There are four methodological forms of multivariate credit scoring models: (1) the linear probability model, (2) the logit model, (3) the probit model, and (4) the multiple discriminant analysis model. All of these models identify financial variables that have significant statistical explanatory power in differentiating defaulting companies from non-defaulting companies.
Some Basic Facts about Binary Response Models
linear probability model: $\operatorname{Pr}(\mathrm{Y}=1)=\mathrm{Xb}+\mathrm{u}$
Suitable for estimating average percentage-point treatment effects in special case of a single dichotomous X . In other applications, can produce out-of-bounds predicted values.

Logistic regression model: $\operatorname{Pr}(\mathrm{Y}=1)=1 /\left(1+\mathrm{e}^{-\mathrm{Xb}}\right)=\mathrm{e}^{\mathrm{Xb}} /\left(1+\mathrm{e}^{\mathrm{Xb}}\right)$
Example: let $-\mathrm{Xb}=1$ :
$\operatorname{Pr}(\mathrm{Y}=1)=1 /\left(1+\mathrm{e}^{-1}\right)=1 / 1.37=.73=\mathrm{e}^{1} /\left(1+\mathrm{e}^{1}\right)=.73$
Another way to think about the logistic regression model is that it is like a regression model in which the log odds, i.e., $\ln (\mathrm{p} /(1-\mathrm{p}))$ are the dependent variable.
$\operatorname{Pr}(Y=1)=\frac{e^{\alpha}}{1+e^{\alpha}}$
$\operatorname{Pr}(Y=1)\left(1+e^{\alpha}\right)=e^{\alpha}$

$$
\begin{aligned}
& \left.\operatorname{Pr}(Y=1)+\operatorname{Pr}(Y=1) e^{\alpha}\right)=e^{\alpha} \\
& \operatorname{Pr}(Y=1)=e^{\alpha}(1-\operatorname{Pr}(Y=1)) \\
& \frac{\operatorname{Pr}(Y=1)}{1-\operatorname{Pr}(Y=1)}=e^{\alpha} \\
& \ln \left(\frac{\operatorname{Pr}(Y=1)}{1-\operatorname{Pr}(Y=1)}\right)=\alpha
\end{aligned}
$$

In other words, logistic regression coefficient (here, an intercept) represents the expected log odds.
Note that there is no disturbance term in this model. However, we can derive a logistic regression specification from a latent variable model in which $\mathrm{Y}^{*}=\mathrm{Xb}+\mathrm{u}$, where u is drawn from a logistic distribution (approximately the same as at distribution with 7 degrees of freedom). We don't observe Y* directly. Instead, we observe Y=1 when $\mathrm{Y}^{*}>0$ and $\mathrm{Y}=0$ otherwise.

Probit regression model: $\operatorname{Pr}(\mathrm{Y}=1)=¥(\mathrm{Xb})$, where $¥($.$) is the cumulative distribution function for a standard$ normal density ( mean $=0$, variance $=1$ )

For example: $¥(0)=.5$. Half of the area of a standard normal density lies to the left of $0 . ¥(1)=.84$ since $68 \%$ of the area on a normal curve lies within 1 standard deviation of the mean; $32 \%$ of the area lies outside 1 SD, so $84 \%$ lies to the left of one standard deviation above the mean.

The probit regression specification has an intuitive basis in a latent variable model. $\mathrm{Y}^{*}=\mathrm{Xb}+\mathrm{u}$, where u is drawn from a normal distribution. Again, we observe $\mathrm{Y}=1$ when $\mathrm{Y}^{*}$ is positive, $\mathrm{Y}=0$ otherwise.

Logistic regression and probit tend to generate very similar predicted values, except at the extremes of the probability scale. Rarely do they generate results that have different substantive or statistical interpretations.

Note also that for bivariate regression models with a binary independent variable, LPM, probit, and logit all give the same predicted values and t -ratios.

We have used the following model:
$Y=\beta_{0}+\beta_{1} \mathrm{X}_{1}+\beta_{2} \mathrm{X}_{2}+\beta_{3} \mathrm{X}_{3}+\beta_{4} \mathrm{X}_{4}+\beta_{5} \mathrm{X}_{5}+\beta_{6} \mathrm{X}_{6}+\beta_{7} \mathrm{X}_{7}+\beta_{8} \mathrm{X}_{8}$
$+\beta_{9} \mathrm{X}_{9}+\beta_{10} \mathrm{X}_{10}+\beta_{11} \mathrm{X}_{11}+\beta_{12} \mathrm{X}_{12}+\beta_{13} \mathrm{X}_{13}+\beta_{14} \mathrm{X}_{14}+\beta_{15} \mathrm{X}_{15}+\beta_{16} \mathrm{X}_{16}$
Where:
X 1 : The loan amount is paid to the customer.
X2 : Guarantee, the amount of collateral received from customers.
X3: Term loans
X4 : Interest rate
X 5 : Industry of the applicant
X6 : Experience with bank
X 7 : Retained earnings to total assets ratio
X 8 : Sales to total assets ratio
X9 : Ratio of total debt to total assets
X10 : Current debt to equity ratio
X11: Current asset turnover ratio
X12 : Current Ratio (Current debts / Current Assets)
X13 : Immediate ratio (the debt / inventory - current assets)
X14 : Return on assets (total assets / net interest))
X15 : Cash flow to debt ratio
X16 : Turnover of total assets (total assets / net sales)

## 3. EMPIRICAL RESULTS

We have estimated logit model. Estimation results were shown by table 3 as following:

Table 3. Estimation Results

|  | Variables | Coefficient | EXP ( $\beta$ ) | Wald test | P-value |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Intercept | 3.9346 | 51,11 | 28.891 | 0.0000 |

|  | Oil | 2.597 | 13.435 | 8.556 | 0.007 |
|  | Building | 2.291 | 9.88 | 4.717 | 0.031 |
|  | $\mathrm{X}_{6}$ | 0.007 | 1.007 | 5.512 | 0/0168 |
|  | $\mathbf{X}_{7}$ | 1.56 | 4.76 | 3.794 | 0.0421 |
|  | $\mathrm{X}_{8}$ | 1.102 | 3.010 | 9.001 | 0.0074 |
|  | X9 | 1.812 | 6.122 | 10.954 | 0.001 |
|  | $\mathrm{X}_{10}$ | 0.006 | 1.006 | 5.096 | 0.0144 |
|  | $\mathrm{X}_{11}$ | 0.0017 | 1.0017 | 4.499 | 0.0361 |
|  | $\mathrm{X}_{12}$ | 1.17 | 3.22 | 3.81 | 0/040 |
|  | $\mathrm{X}_{13}$ | 1.69 | 5.419 | 9.032 | 0.0077 |
|  | $\mathrm{X}_{14}$ | 1.247 | 3.479 | 10.817 | 0.001 |
|  | $\mathrm{X}_{15}$ | 0.018 | 1.018 | 5.121 | 0.0285 |
|  | $\mathrm{X}_{16}$ | 1.95 | 7.02 | 8.765 | 0.0041 |

Estimated equation is as:
$\mathrm{Y}=\ln (\mathrm{p} / \mathrm{p}-1)=3.93+0.001 \mathrm{X} 1+1.661 \mathrm{X} 2+1.207 \mathrm{X} 3+0.007 \mathrm{X} 4+(2.762 \mathrm{X} 51+1.903 \mathrm{X} 52+2.597 \mathrm{X} 53+2.291$
$\mathrm{X} 54)+0.007 \mathrm{X} 6+1.56 \mathrm{X} 7+1.102 \mathrm{X} 8+1.812 \mathrm{X} 9+0.006 \mathrm{X} 10+0.0017 \mathrm{X} 11+1.17 \mathrm{X} 12+1.69 \mathrm{X} 13+1.247 \mathrm{X} 14$
$+0.018 \mathrm{X} 15+1.95 \mathrm{X} 16$
All of the coefficients are significant at $95 \%$ confidence level.
Table 4. Goodness of Fit Statistics

The value of the collateral, and one of the important variables that affect the quality of facilities in default or not default, the estimated model plays a fundamental role.

Variable period of repayment of the facilities is the main parameters related to credit risk customers legal EN Bank.

Variable "interest rate facilities", in relation to credit risk has little effect.
Industrial type of loan in which the applicant is one of the most important factors affecting the credit risk of customers.

Experience with bank has a significantly positive effect on the probability of a no default facility to default.
Ratio of retained earnings to total assets is the main factor of financial ratios affecting the credit risk.
Sales to total assets ratio of financial ratios has a significantly effect on credit risk.
The ratio of debt is considered very influential financial ratios on credit risk and it is the second effectiveness factor.

Current debt to equity ratios of financial ratios has a minimal impact on credit risk.
Capital ratio of financial ratios has a negligible impact on the credit risk.
Current ratio equals current assets to current liabilities of the financial ratios have a significant impact on credit risk.

Immediate relative of important financial ratios has a significant effect on credit risk.
Return on assets has a significant positive effect on credit risk.
Cash flow to debt ratio has a significant positive effect on credit risk.
Turnover of total assets is one of the most important factors on credit risk.
Reliance on bank and prioritization of the variables influencing the bank's credit risk in relation to legal Customers are:

1. Type of Industry of the applicant
2. Turnover of total assets
3. Ratio of total debt to total assets
4. Immediate ratio (the debt / inventory - current assets)
5. Retained earnings to total assets ratio
6. Guarantee, the amount of collateral received from customers
7. Return on assets (total assets / net interest)
8. Term loans
9. Sales to total assets ratio
10. Current Ratio (Current debts / Current Assets)
11. Interest rate
12. Cash flow to debt ratio
13. Experience with bank
14. Current debt to equity ratio
15. The loan amount is paid to the customer
16. Current asset turnover ratio

Prediction Evaluation of model is considered by following table:
If the facilities granted to a customer's IRR increases the probability of a no default facility to default is 1 . Variable "loan" has not an important impact on credit risk

Table 7. Expectant probability threshold

| Dependent Variable: Y |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| \% Correct | 87.50 | 98.69 | 95.80 | 100.00 | 0.00 | 24.51 |
| \% Incorrect | 12.50 | 1.31 | 4.2 | 0.00 | 100.00 | 75.49 |
| Total Gain* | -12.00 | 98.69 | 45.80 |  |  |  |
| Percent Gain** | NA | 98.69 | 91.60 |  |  |  |

310 cases to assess the predictive power of the model and test data are used to estimate power and performance of the model and type II errors can be determined. The left side of the table, the predicted probability values for the dependent variable Y (the fitted equation) based on the higher or lower than the threshold are observed in the actual amounts are classified. In the table, the observations demonstrate the possibility of using the same sample of observations is $\mathrm{Y}=1$, are classified. This probability is constant during the observations, numerical model, which estimates that only include the width of the source is C , is calculated.

Results indicate that 70 cases ( $92 \%$ of the total 76 cases) classified correctly in observations $\mathrm{Y}=0$ (lack of timely repayment of the facility) and 227 cases ( $97 \%$ of the total 234 ) in observations $\mathrm{Y}=1$ (timely repayment of the facility).

In general, the model can fit $87.5 \%$ of all observations $\mathrm{Y}=0$ and $98.7 \%$ percent of all observations $\mathrm{Y}=1$, which has accurately predicted. The model is called the degree of sensitivity equal to $87.5 \%$ and the detection rate equal to $98.7 \%$ percent.

## Customer rating system for EN Bank:

Y value for each customer is calculated as follows:
Table 8. Customers rating

| $\wedge$ | Customer | $\wedge$ | Customer | $\wedge$ | Customer |  | Customer |  | Customer |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Source: Researchers Findings
Then, we calculated probability of no default by following formula:

$$
\hat{Y}_{i}=\ln \left(\frac{\hat{p}_{i}}{1-\hat{p_{i}}}\right)
$$

$$
\hat{p}_{i}=\frac{\mathrm{e}^{\mathrm{y}}}{1+\mathrm{e}^{\mathrm{y}}}
$$

Source: Research findings

Bank based on the probability of default can take decision on a grant or denial of the facility to customers.

## 4. Conclusion

In this paper, we have used Logit regression for EN Bank's credit rating. 310 cases to assess the predictive power of the model and test data are used to estimate power and performance of the model and type II errors can be determined.

Reliance on bank and prioritization of the variables influencing the bank's credit risk in relation to legal Customers are:

1. Type of Industry of the applicant
2. Turnover of total assets
3. Ratio of total debt to total assets
4. Immediate ratio (the debt / inventory - current assets)
5. Retained earnings to total assets ratio
6. Guarantee, the amount of collateral received from customers
7. Return on assets (total assets / net interest)
8. Term loans
9. Sales to total assets ratio
10. Current Ratio (Current debts / Current Assets)
11. Interest rate
12. Cash flow to debt ratio
13. Experience with bank
14. Current debt to equity ratio
15. The loan amount is paid to the customer
16. Current asset turnover ratio

Results indicate that 70 cases ( $92 \%$ of the total 76 cases) classified correctly in observations $\mathrm{Y}=0$ (lack of timely repayment of the facility) and 227 cases ( $97 \%$ of the total 234 ) in observations $\mathrm{Y}=1$ (timely repayment of the facility).

In general, the model can fit $87.5 \%$ of all observations $\mathrm{Y}=0$ and $98.7 \%$ percent of all observations $\mathrm{Y}=1$, which has accurately predicted. The model is called the degree of sensitivity equal to $87.5 \%$ and the detection rate equal to $98.7 \%$ percent.
